Class 13: RNA Seq Analysis

Olivia Baldwin

Today we will work with bulk RNASeq data from Himes et al. where airway smooth muscle (asm) cells were treated with dexamethasone (dex), a glucocorticoid steriod.

```
counts <- read.csv("airway_scaledcounts.csv", row.names = 1)
meta <- read.csv("airway_metadata.csv")

head(counts)
```

```

```
[1] 38694     8
```

```
table(meta$dex)
```

```
control treated
      4       4
```

Q1: There are 38,694 genes in the `counts` data.

Q2: There are 4 control samples and 4 treated samples.

Want to compare control vs treated to see the drug's affect.

1. Let's split the counts into `control.counts` and `treated.counts`.

```
meta$id == colnames(counts)
```

```
[1] TRUE TRUE TRUE TRUE TRUE TRUE TRUE TRUE
```

Syntax for [] is [rows, columns]

```
control <- meta[meta$dex=="control",]
control.counts <- counts[,control$id]
```

```
treated <- meta[meta$dex == "treated",]
treated.counts <- counts[,treated$id]
```

2. Lets calculate the mean counts per gene for "control" and "treated" - then we can compare.

I can use the `apply` function to apply `mean` over the rows or columns of a data frame.

```
control.mean <- apply(control.counts, 1, mean)
head(control.mean)
```

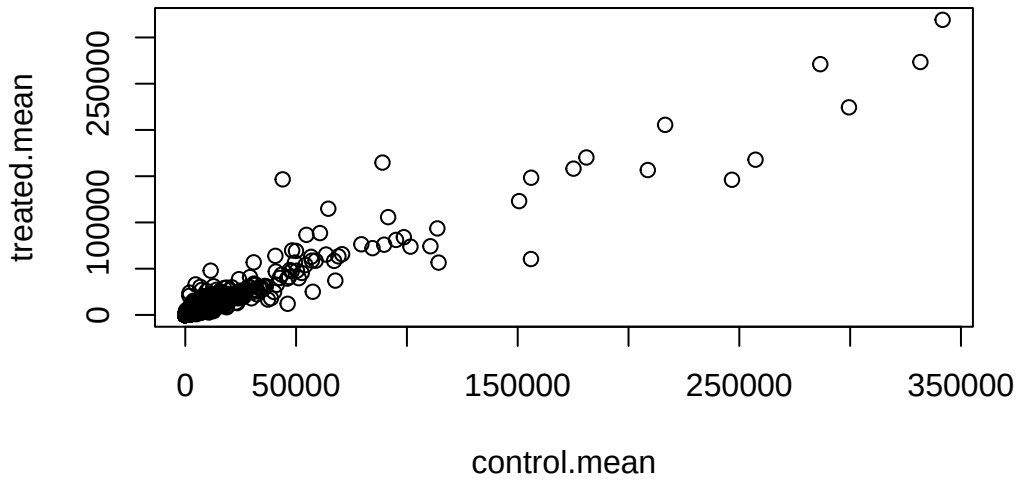
```
ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
         900.75            0.00          520.50          339.75           97.25
ENSG00000000938
           0.75
```

```
treated.mean <- apply(treated.counts, 1, mean)
head(treated.mean)
```

```
ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
         658.00            0.00          546.00          316.50           78.75
ENSG00000000938
           0.00
```

Put these mean counts together into one df for ease.

```
meancounts <- data.frame(control.mean, treated.mean)
plot(meancounts)
```

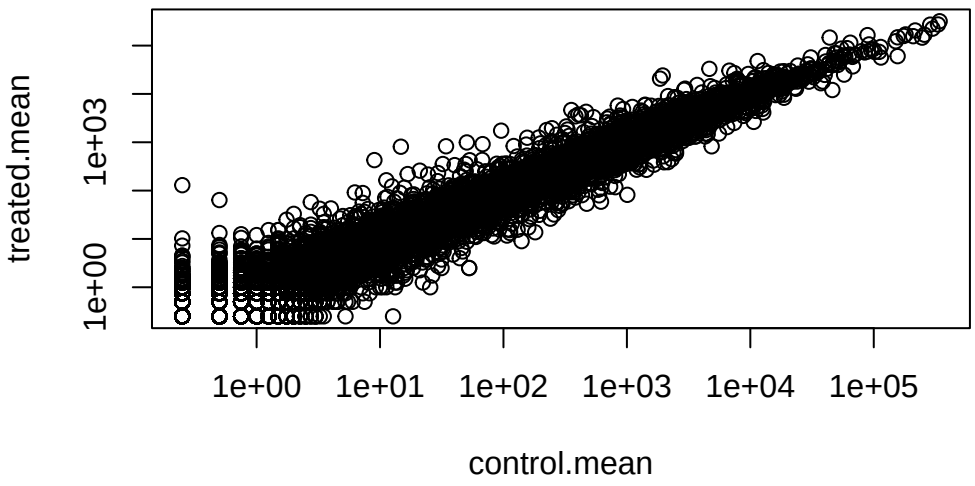


Let's log transform it so we can see more of our data points.

```
plot(meancounts, log="xy")
```

```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted
from logarithmic plot
```

```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted
from logarithmic plot
```



We most often use log2 transforms here because it makes the math easier.

This is because the log2 of 1 is zero (no change). A 1 would mean a "doubling" of the amounts.

```
#log2(treated/control)
log2(10/10)
```

```
[1] 0
```

```
log2(10/20)
```

```
[1] -1
```

```
log2(20/10)
```

```
[1] 1
```

```
log2(40/10)
```

```
[1] 2
```

Let's calculate the log2 fold change and add it to our table `meancounts`.

```
meancounts$log2fc <- log2(meancounts$treated.mean/meancounts$control.mean)
head(meancounts)
```

```
                control.mean treated.mean      log2fc
ENSG00000000003       900.75       658.00 -0.45303916
ENSG00000000005         0.00         0.00         NaN
ENSG00000000419       520.50       546.00  0.06900279
ENSG00000000457       339.75       316.50 -0.10226805
ENSG00000000460        97.25        78.75 -0.30441833
ENSG00000000938         0.75         0.00        -Inf
```

Filter out all of the 0 counts from the `meancounts` data.

```
to.rm <- rowSums(meancounts[,1:2] == 0) > 0
mycounts <- meancounts[!to.rm, ]
#the `!` means opposite of

nrow(mycounts)
```

```
[1] 21817
```

```
#this shows that there are only about 22000 genes left after all 0 counts removed
```

> Q: How many down regulared genes do we have at the common log2 fold change value of below -2? **367**

```
down <- mycounts$log2fc < -2
sum(down)
```

```
[1] 367
```

> Q: How many up regulated genes do we have at log2 of higher than +2? **250**

```
up <- mycounts$log2fc > 2
sum(up)
```

```
[1] 250
```

Do we trust these results? Not yet...

We are missing the stats!!

##DESeq Analysis

```
library(DESeq2)
```

```
dds <- DESeqDataSetFromMatrix(countData = counts,
                              colData = meta,
                              design = ~dex)
```

```
converting counts to integer mode
```

```
Warning in DESeqDataSet(se, design = design, ignoreRank): some variables in
design formula are characters, converting to factors
```

The main function in DESeq2 is called `DESeq()`.

```
dds <- DESeq(dds)
```

```
estimating size factors
```

```
estimating dispersions
```

```
gene-wise dispersion estimates
```

```
mean-dispersion relationship
```

```
final dispersion estimates
```

```
fitting model and testing
```

```
res <- results(dds)
```

```
res
```

```
